## INTRODUCTION

## FACTORS OF LOSS IN WEIGHT

Tobacco loses weight, as a rule, from the time it leaves the hands of the growers until it is placed in process of manufacture. Since the statistics of tobacco are widely used and are interpreted from varying points of view, the consideration of these losses in weight is important. The purpose of this circular is to analyze the factors causing shrinkage and losses in weight and to make a practical application of the uses of these factors in the statistics of tobacco held in storage.

The factors of loss in weight are (1) losses of particles of dirt and tobacco in cleaning and packing, (2) reduction in moisture content and chemical changes during fermentation, and (3) loss due to removal of stems or midribs of the leaves.

Losses of these kinds occur to some degree in the handling and storage of practically all tobacco. The percentage of loss varies not only for different types of tobacco, but in each type the rate of loss under any one of the factors enumerated varies for different grades and for tobacco of different crop years. The percentage of loss also depends upon climatic conditions, marketing procedure, handling and packing methods, location, nature, and duration of storage, and natural and artificial fermentation processes.

Under the first factor of loss in weight-cleaning and packingthere is the loss of foreign matter, particularly dirt and sand, particles

[^0]of which adhere to the gummy surfaces of the tobacco leaves and are shaken off in the various handling processes. There is also some loss due to the breaking off of small pieces of leaf when the tobacco is handled in dry condition. Foreign-matter loss is negligible in some types but in the lower grades of other types it may average from 2 to 3 percent. It is not given separate consideration in the tables on losses but is included in the figures on dirt and sand and moisture losses.

Under the second factor of loss in weight-reduction in moisture content and chemical change during fermentation-there is the actual loss in moisture which occurs in the handling, redrying, and packing operations and in the sweating or fermentation processes. In some types of tobacco the greatest moisture loss occurs during the preliminary redrying and handling operations and in others the greatest loss occurs during the sweating or fermentation period.

Some types of tobacco are marketed with a moisture content as high as 35 percent but will mold if packed in this condition. This is particularly true of the types grown generally in the Southern States. To avoid molding, the tobacco is removed to a redrying plant soon after sale, where it passed through a redrying machine which conditions it for packing, or it is hung in tiers and air-dried.

Tobacco goes through a sweat each year. The term "sweat" is applied to the natural fermentation process that occurs in the spring and summer. Fermentation and aging eliminate the acrid pungency and bite of new tobacco and give it a sweeter, mellower flavor.

During the fermentation process tobacco undergoes chemical changes similar to those that take place in any closely packed, moist vegetable matter. The temperature rises and certain volatile products and convertible solids are thrown off. The tobacco appears to take on additional moisture and becomes soft and pliable. In addition to the chemical losses, there is actually a loss of moisture when the sweating period is finished.

Under the third factor, there is the loss in weight from the removal of the stems or midribs. The stem or midrib is excluded from most manufactured tobacco products because of its coarse, fibrous, woody, and more or less flavorless nature. In the manufacture of snuff the whole leaf is usually ground, and in some cases more stems are added. In the manufacture of some smoking tobacco the stems are removed, rolled flat under pressure, and cut finely, and a certain percentage is added to the cut leaf.

The stemming loss varies according to the proportion of the stem removed and according to the type of tobacco. For some tobacco products it is necessary to remove the entire stem, from the tip of the leaf to the butt. For other products, it is necessary to remove only a few inches of the coarser part of the stem nearest the butt of the leaf.

The variation in loss as to type is due to the relative size or coarseness of the stem in proportion to the leaf surface. Stems are removed from some tobacco prior to packing, fermentation, and storage, but the greater part is packed in leaf or unstemmed form and the stems are removed just before the time the tobacco enters the manufacturing processes.

## RELATION OF PACKING AND STORAGE METHODS TO LOSS IN WEIGHT

Practically all southern tobacco, or types other than cigar-leaf, is packed in hogsheads for storage and shipment. A limited quantity
is packed in boxes, for example, Black Fat. A hogshead is a large cask or barrel made of lightweight thin staves. The dimensions vary for different types of tobacco. Whether packed in leaf form (unstemmed) or strip form (stemmed) all hogshead-packed tobacco is aged before it is used in manufactured products. It is never used until it has gone through at least one sweat. Most of it is aged for 2 or more years. The length of time it remains in storage depends upon manufacturers' needs and upon the nature and characteristics of the crops of certain years.

Hogsheads of tobacco are stored in warehouses built especially for tobacco storage, and are usually stacked in tiers two or three hogsheads high in the manner shown in figure 1. Various types of construction are used for storage warehouses in the South. There are one-story, two-story, and three-story warehouses of wood, brick, concrete, and steel. The most modern and most popular type of construction is the single-story steel or wood frame sheathed and roofed with metal.

Figure 1.-Interior view of warehouse. Hogsheads of tobacco in storage.
The sides are flared outward within 4 or 5 feet of the ground, and in the offset thus formed, heavy screen wire is placed for ventilation (fig. 2).

The change in weight of southern tobacco in storage varies with the construction and with the location of the warehouses. For example, in a two-story warehouse, tobacco stored on the upper floor may show a loss at the end of the first year, whereas that stored in the basement may show a slight gain. Tobacco stored at inland points may show a loss and that stored near the seaboard may show a gain.

In packing domestic cigar-leaf tobacco for storage and shipment, the filler types are packed in wooden cases, bales, or barrels, the binder types, in cases and bales, and the wrapper types only in bales. The dimensions and weights of cases and bales will be discussed separately for each type.

All of the cigar-leaf types, with the exception of Georgia and Florida sun-grown and Puerto Rican, are packed in unstemmed form, and the storage, aging, and fermentation are under more definite control than is the case in southern types. The principal difference is that all southern hogshead tobacco is stored in warehouses and permitted to go through the sweat under natural atmospheric conditions, whereas cigar-leaf tobaccos are usually sweated and stored in warehouses in which the temperature is controlled and sometimes the humidity. When definite temperature control is practiced it is
spoken of as "force sweating." The fermentation process is an important part of the preparation of cigar-leaf tobacco for manufacture.

Another distinction is that in most of the southern hogshead tobaccos the heaviest losses in weight occur in the initial conditioning, handling, and packing, whereas in most of the cigar-leaf tobaccos the heaviest losses occur after packing, during the storage and fermentation periods. In some types of cigar-leaf tobacco, bulk-sweating prior to packing is practiced by all dealers and packers, and in other types by only a limited number.

Figure 2.-Exterior view of modern storage warehouse.
REPORTS ON STOCKS OF LEAF TOBACCO
An act of Congress approved April 30, 1912, directed the Bureau of the Census to collect and publish statistics of leaf tobacco in the United States held by certain classes of manufacturers and dealers in leaf tobacco. The original act, providing for reports as of April 1 and October 1 of each year, was amended by an act of Congress approved May 10, 1916, requiring reports also as of January 1 and July 1 of each year.

The Bureau of the Census therefore collected statistics of leaf tobacco held at the beginning of each quarter from dealers in leaf tobacco and from manufacturers who, according to the returns of the Commissioner of Internal Revenue, manufactured during the preceding calendar year more than 50,000 pounds of tobacco or snuff, 250,000 cigars, or $1,000,000$ cigarettes. Stocks of leaf tobacco held by tobacco growers' cooperative associations were also included. The tables on stocks of leaf tobacco in this circular were compiled from reports of the Bureau of the Census up to and including January 1, 1929.

An act of Congress approved January 14, 1929, transferred the collection and publication of statistics on leaf tobacco to the United States Department of Agriculture. This law was amended by acts of Congress approved July 14, 1932, and August 27, 1935. The general provisions of these laws are substantially the same as the original act and amendment, except that reports are required in more detail. The statistics are collected and compiled on the basis of the type classification established and promulgated by the Secretary of

Agriculture. This type classification differs slightly from the classification used by the Bureau of the Census. For example, the fluecured tobacco is subdivided into four types, the fire-cured of Kentucky and Tennessee into three types, the Ohio cigar-filler into three types, the Wisconsin cigar-binder into two types, and other changes are made classifying tobacco on a type basis rather than a State basis.

## APPLICATION OF CONVERSION FACTORS TO STOCKS OF LEAF TOBACCO

The laws under which the Bureau of the Census and the Department of Agriculture have collected and compiled statistics on stocks of leaf tobacco required that the quantity of unstemmed leaf and stemmed leaf be shown. The Bureau of the Census also required that tobacco be reported either on an actual-weight or a marked-weight basis. In arriving at the total quantity of any given type, marked and actual weights were combined; also unstemmed and stemmed weights were combined. The results in either case are misleading as no consideration is given to shrinkage losses in storage, or to stemming losses.

Statistics showing the stocks of leaf tobacco are important, not only to the tobacco trade but to others interested in current and prospective developments affecting tobacco growers, and they are necessary in computations of annual consumption and disappearance of particular types. Serious difficulties arise in making such computations, because of the varied forms in which leaf-tobacco stocks are reported.

To arrive at definite consumption figures, stocks should be converted to a farm-sales-weight basis-the equivalent of the weight at the time of sale by the grower-thereby making the figures of leaf-tobacco stocks comparable with figures of leaf-tobacco production. The stemmed leaf reported should be converted to an unstemmed basis, taking into account the loss due to the removal of the stem. Then adding this to the unstemmed leaf reported, the total should be converted to a farm-sales-weight basis, taking into account the average losses in handling and shrinkage. Stocks of the different types of tobacco as reported to the Bureau of the Census and to the Department of Agriculture have been converted on this basis and are shown in tables 4 to 30, inclusive, of the Appendix.

In the analysis of stocks it is important that consideration be given to the normal movement of tobacco from growers' hands into the hands of dealers and manufacturers. The marketing period varies with the different types and will be treated in the separate type discussions.

The average loss figures quoted in tables 1 and 2 are the result of a study covering a period of several years. Questionnaires were mailed to all manufacturers and dealers who file quarterly reports of stocks of leaf tobacco. The average losses derived from a compilation of these questionnaires were then carefully checked with the year-to-year records of leading manufacturers and dealers throughout the United States.

## PROGRESSIVE LOSSES AND CONVERSION FACTORS

In obtaining average losses in weight where two or more methods of handling are practiced, the loss resulting from each method of handling was weighted by the approximate percentage of the crop so handled. For example, in the case of flue-cured tobacco, in calculating conversion factors consideration was given to the approximate percentage of the
crop packed in both domestic and export order, and in the case of cigar leaf, to the various methods of handling, packing, and sweating each of the various types. Consideration was also given to the length of time each of the various types remains in storage and the approximate percentage of the tobacco reported in stocks on "marked", or packed, and on "actual". weight basis.

In calculating conversion factors the percentage of loss in storage is not applied to the original farm weight, but to the residual weight as losses occur progressively. For example, where the initial loss from dirt, sand, and redrying in handling flue-cured tobacco is 10 percent, and the first year's loss in storage is 1 percent, the calculation is made on the basis of taking 1 percent of the 90 pounds which remain after deducting handling and redrying loss. The percentage of stemming loss is applied to 100 pounds regardless of whether it is farm weight, storage-order weight, or processing weight. The variation in actual stemming losses, depending upon the time tobacco is stemmed, has been taken into consideration in calculating conversion factors.

Tables 1 and 2 show the progressive losses for each type, and table 3 shows the conversion factors.

## FLUE-CURED, TYPES 11-14

In dealing with losses in weight, the four types of flue-cured tobacco may be considered as a whole, as there is little difference between them. Flue-cured tobacco, which is also known as Bright, Bright Yellow, and Virginia Bright, is produced in the piedmont section of Virginia and North Carolina, and the coastal plains of North Carolina, South Carolina, Georgia, and northern Florida. (See map of tobacco-growing districts, fig. 3.)

Flue-cured tobacco is the principal kind of tobacco grown in the United States, usually comprising from 50 to 60 percent of the total crop of all types. It ranges in color from a bright lemon yellow to a dark reddish orange and in some cases to a reddish brown or a dark brown known as mahogany. The light colors predominate and the thinner, light-bodied tobacco is preferable for cigarette and smoking tobacco. The darker, heavy-bodied grades are used in the manufacture of chewing tobacco. About 40 percent of all flue-cured tobacco is used in domestic manufacture and about 60 percent is exported.

Practically all flue-cured tobacco is harvested by the priming method. As the leaves ripen they are picked from the stalk in successive operations, beginning at the bottom of the plant. They are cured by applying regulated heat through furnaces and flues built into the barns. After being cured the leaves are sorted into lots on the basis of quality and color and tied in small bundles or hands of 10 to 20 leaves. In Georgia and Florida the leaves are not tied into hands but are marketed loose.

The auction sales system of marketing prevails throughout the flue-cured tobacco area. ${ }^{2}$ The marketing period usually begins the latter part of July and extends through the greater part of February of the following year. The markets for type 14 in Georgia open first, usually in the latter part of July-sometimes early in August.

${ }^{1}$ Example of application: To convert 127,975 pounds of stemmed flue-cured tobacco to unstemmed weight, multiply by 1.282 ; that is, 127,975 pounds $\times 1.282=164,064$ pounds. Except for the first column, the factors have been rounded to the nearest five-thousandths

They continue to sell for about 6 weeks. The markets for type 13 in South Carolina and southern North Carolina open about the middle of August and continue selling through October, with the bulk of the sales occurning prior to October 1. The markets for type 12 in North Carolina open about September 1 and continue selling through Jan-

Figure 3.-Map of tobacco-growing districts.
uary of the next year. The markets for type 11 in North Carolina and Virginia open, as a rule, in the second or third week in September and continue to sell through February of the next year. Considering flue-cured tobacco as a whole the peak of sales is some time in October or November, and the greatest movement from farmers' hands to dealers and manufacturers occurs between October 1 and January 1.

$$

$$

Flue-cured tobacco is delivered by the growers to the auction-sales floors with a moisture content of from 20 to 25 percent, and in some cases in excess of 25 percent. This moisture content tends to prevent breakage in handling. The tobacco is arranged in flat baskets about 4 feet square which are placed in rows on the auction-sales warehouse floor. As the buyers pass along between the rows they examine each lot, frequently pulling hands from the pile on each basket. If the tobacco were not soft and pliable there would be considerable injury by breakage (fig. 4).

Flue-cured tobacco with a moisture content of 20 to 25 percent would mold if packed directly in hogsheads. To avoid this, the tobacco is removed from the floor as soon as the sale is over and is delivered to the redrying plant of the buyer. There it is assorted and

Figure 4.-Baskets of tobacco on warehouse floor ready for sale at auction.
blended according to grade and run through a redrying machine. Practically all the original moisture is removed in this machine and a desired amount is added to condition the tobacco for packing without breakage and to allow it to go through the natural fermentation process or sweat while in storage without damage by mold. This redrying process also distributes the moisture uniformly.

Redrying machines consist of a series of large chambers in which the temperature and humidity are regulated. A chain conveyor moves slowly through this series of chambers. Generally the hands of tobacco are hung on sticks about 4 feet long and the sticks are placed on the chain conveyor. As the tobaceo on these sticks enters thefirst chamber, fans force a current of hot dry air through it, eliminating practically all the moisture. In the next chamber the temperature is lowered somewhat, and in the succeeding chamber or chambers,
which are humidified by means of fine sprays of water or live steam, the tobacco absorbs the desired amount of moisture (fig. 5).

After the tobacco has gone through the redrier, it is packed in hogsheads for storage or shipment. Hogsheads about 48 inches in diameter and 54 inches in depth are used in packing flue-cured tobacco for domestic trade, and 48 inches in diameter and 48 inches in depth in packing for export trade. The packing is usually done in the following way: A hogshead is placed on a round dolly or truck conveniently near the rear end of the redrying machine. As the tobacco emerges from the redrier, it is removed from the sticks and placed in layers with the heads or butts of the hands outward until the hogshead is filled. Then an especially made open cylinder of the same diameter is placed above the filled hogshead and the process of packing is continued until this also is filled. The dolly, together with the filled hogshead and cylinder, is then rolled under a hydraulic press.

Figure 5.-Type of machine used in redrying tobacco.
The tobacco is compressed through the cylinder and into the hogshead and a head is nailed in place. This operation is called prizing. The average net weight of a hogshead of flue-cured tobacco is about 1,000 pounds, ranging from 900 to 1,100 pounds. The weight of an empty hogshead ranges from 135 to 150 pounds. A tobacco-prizing operation (in type 22) is illustrated in figure 6.

In the process of assorting, handling, redrying, and packing there is an average loss in weight, due to the shaking off of dirt and sand particles which adhered to the tobacco leaves, of about 2 percent. This dirt and sand loss is negligible in the handling of the upper leaves and better quality tobacco, but runs above 2 percent in the handling of "first primings" and low-grade lugs. Buyers whose purchases consist mainly of lower-grade tobaccos may have a dirt and sand loss of 5 to 6 percent. Some firms buy sweepings and loose leaves raked up from the curing barn and warehouse floors and run them over a wire screen for cleaning prior to redrying. Such pur-
chases sometimes show a dirt and sand loss as high as 30 percent. However, losses from this source, considering all grades, average about 2 percent.

An additional loss in weight, due to the removal of moisture, occurs in the redrying process, running from 8 to 10 percent. The percentage of moisture loss varies during the marketing season according to weather conditions and the quality or grade of tobacco handled. It also varies with crop years. When packed for export, tobacco usually contains about 11 percent of moisture, and when packed for domestic trade, from 12 to 14 percent. The total loss in weight in the rehandling and redrying of flue-cured, including dirt and sand losses and moisture losses, considering all grades over a period of years, averages about 10 percent for tobacco packed in domestic order and about 12 percent for that packed in export order.

The stem is removed from some flue-cured tobacco prior to redrying and packing, but most of it is packed in leaf form and the stem

Figure 6.-Tobacco-prizing operation. Hogsheads along the sides of the pit are being packed with tobacco. Note the extra container placed on top of hogshead.
is removed at a later date. The loss in stemming flue-cured tobacco ranges from 16 to 28 percent. This range is due to some extent to difference in quality of the leaf and the relative weight of the stem in proportion to the total leaf. It is due principally to the quantity or portion of the stem removed. The average loss in stemming fluecured tobacco is about 22 percent.

Formerly the stem was removed from a large part of the tobacco entering into foreign trade, especially that going to the United Kingdom, but during recent years the quantity stemmed before export has been reduced substantially. At present, only a very small percentage is stemmed prior to export.

Flue-cured tobacco has relatively light losses in storage. In some cases it gains weight in storage. Considering the weight gains and losses, the average loss in storage is about 1 percent the first year, 0.5 percent the second year, and is negligible thereafter. Table 1 shows the various weight losses on flue-cured tobacco progressively.

The average net yield from 100 pounds of farm-sales weight flue-cured tobacco is approximately 69 pounds of stemmed leaf ready for manufacturing purposes.

## VIRGINIA FIRE-CURED, TYPE 21

Virginia fire-cured tobacco is also known as Virginia dark-fired or Virginia dark. It is produced in the piedmont and mountain sections of Virginia in the area adjacent to Lynchburg, Bedford, Farmville, and Blackstone. About 75 percent of it is exported and about 25 percent is used by domestic manufacturers. The principal domestic usage is for the manufacture of snuff. Certain quantities go into smoking tobacco, chewing tobacco, Italian-type cigars, and Black Fat. ${ }^{3}$

Virginia fire-cured tobacco usually comprises from 1 to 2 percent of the United States crop. This type is dark in color and is heavybodied compared with flue-cured tobacco. The color ranges from a light brown to a very dark brown. The darker, heavier bodied grades are desirable for use in manufacturing snuff.

Virginia fire-cured is harvested by the stalk-cutting method. The stalk is split from the top to within 8 or 10 inches of the ground and the plant is then chopped off near its base. After the plant has wilted the split stalk is straddled over a lath or tobacco stick and is carried to the curing barn. From 8 to 10 plants are placed on each stick, depending on the size of the plants. In fire-curing tobacco, the smoke and fumes from wood fires built on the earth floor of the curing barn come in direct contact with the tobacco and impart a desirable flavor. After the tobacco has cured and during a damp season when the dried leaves have absorbed sufficient moisture to permit their being handled without breakage, it is taken down from the tiers in the barn and the leaves are stripped from the stalk, assorted according to quality, color, and length, and tied into hands.

Virginia fire-cured tobacco is marketed principally under the auc-tion-sales system in a manner similar to flue-cured tobacco. The marketing season usually begins about the middle of November and extends through the greater part of March of the following year. Most of the sales are in December and January. Because of the heavy body and the more or less preservative nature of the method of curing, this type is usually marketed in much higher order, or with a greater moisture content, than some other types.

The moisture content of Virginia fire-cured ranges from 25 to 35 percent at the time it is delivered to market. After being sold it is put through a redrying machine in the same way as flue-cured tobacco and packed in hogsheads averaging approximately 1,050 pounds net when packed for English trade, and approximately 1,350 pounds net when packed for domestic trade, or for foreign trade other than to the United Kingdom. This type is usually packed for domestic trade and foreign trade other than to the United Kingdom with approximately 14 percent moisture. Because of the requirements of customs laws and a high rate of import duty, it is packed for the English trade with approximately 11 percent moisture content.

The average dirt and sand loss in handling is about 1 percent. The average loss in redrying for domestic use is about 14 percent and for export about 16 percent. This loss in handling, redrying, and packing

[^3]ranges from 10 to 20 percent, varying according to the grade or quality of the tobacco, weather conditions, and crop years.

Virginia fire-cured tobacco is stored and aged in the same way as flue-cured tobacco, and goes through similar fermentations in the spring of each year. The loss in weight during the first year of storage is about 1 percent, during the second year about 1 percent, and during the third year about 0.5 percent. The total loss in weight while in storage runs slightly higher than for flue-cured partly because firecured is stored mostly at inland points and partly because it goes through a harder sweat the second year than does flue-cured, and sweats some even in the third year.

The loss in stemming Virginia fire-cured tobacco usually ranges from 20 to 26 percent, with an average loss of about 23 percent, but as its most important domestic use is in the manufacture of snuff, very little is stemmed.

At present a small percentage of that part going to foreign countries is stemmed, although formerly the greater part of it was stemmed prior to export.

## KENTUCKY AND TENNESSEE FIRE-CURED, TYPES 22 AND 23

Type 22 fire-cured tobacco is produced in a section east of the Tennessee River in southern Kentucky and northern Tennessee. The principal markets for this type are Springfield and Clarksville, Tenn., and Hopkinsville, Ky. Type 23 fire-cured tobacco is produced in a section between the Tennessee, Ohio, and Mississippi Rivers in western Kentucky and northwestern Tennessee. The principal markets for this type are Mayfield, Paducah, and Murray, Ky.

These types are also known as dark-fired or Kentucky and Tennessee darks. The general characteristics and the marketing and handling methods of the two types are so similar that for the purpose of dealing with losses in weight they may be considered together. The annual production has ranged from around $100,000,000$ pounds to about $150,000,000$ pounds in the last 10 years and is usually about 8 percent of the total crop. The usage is very similar to that of Virginia fire-cured, type 21. From 70 to 75 percent is exported and the rest is used by manufacturers in the United States. The principal domestic usages are for snuff and Italian-type cigars. The color range is about the same as for Virginia fire-cured-from a light brown to a very dark brown. Some grades are comparable with grades of Virginia fire-cured, but more heavy-bodied, somewhat coarser tobacco is produced in Kentucky and Tennessee than in Virginia.

The stalk-cutting method of harvesting is employed in the Kentucky and Tennessee fire-cured territory, and the open-fire method of curing is used. The fires in the curing barns as a rule are kept burning for a period of 3 to 6 weeks. The cured product is usually assorted by the growers into three groups designated either as trash, lugs, and leaf, or as lugs, seconds, and leaf. Some growers make further separations on the basis of color or length.
Most of the tobacco of these types is now marketed under the auction-sales system but considerable country buying still is done. The term country buying covers direct sales by growers on the premises of the grower. Some buyers ride through the country and inspect the crops in the barn, and, if a price agreement can be reached with the grower, contracts are made and the tobacco is delivered direct to the
prizery, or packing house, of the buyer. A part of this tobacco is also marketed through a growers' cooperative association. The auction markets for these types sometimes open early in December, but as a rule they open either about the middle of December or the first of January. The country buying is usually done before the opening of the markets and early in the sales season. The auctionsales floors and the associations usually operate until about the middle of May.

The moisture content of these types is considerably lower than that of Virginia fire-cured when delivered to the market. No definite tests hare been made by the United States Department of Agriculture on moisture content at time of delivery, but information received from

Figure 7.-Fire-cured tobacco of type 22 hung in tiers for air-drying.
buyers and packers of these types indicates that the moisture content at that time ranges from 18 to .22 percent.

The tobacco of these types is conditioned and packed under three general degrees of moisture content or order, known in the trade as English order, continental order, and domestic order. In packing for English order the moisture content is reduced to about 11 percent either by running the tobacco through a redrying machine or by airdrying. ${ }^{4}$ In packing for continental, or stiffened, order the tobacco is air-dried to a point at which it contains about 13 or 14 percent of moisture (fig. 7). In packing for domestic order, or winter order as it is sometimes known, the tobacco is packed in practically the same order as it is received from the farmers. Tobacco handled and packed in English order will lose from 10 to 12 percent in the process. Tobacco handled and packed in continental, or stiffened, order will lose about 5

[^4]percent. Tobacco packed in domestic, or winter, order will lose from 1 to 2 percent.

The loss in weight from dirt and sand in handling these types is so low as to be almost negligible. The average dirt and sand loss does not exceed 0.5 percent.

Kentucky and Tennessee fire-cured tobacco is packed in hogsheads slightly larger than those used in the packing of flue-cured and Virginia fire-cured, and the average weight per hogshead is about 1,450 pounds net. It is stored in warehouses in the same way as flue-cured and Virginia fire-cured, except that it is never racked more than two tiers high. The storage loss of these types of tobacco packed in the English order averages about 1.5 percent the first year, 1 percent the second year, and 0.5 percent the third year. When packed in continental, or stiffened, order the storage loss averages about 2 percent the first year, 1.5 percent the second year, and 1 percent the third year. When packed in domestic, or winter, order the storage loss averages about 4 percent the first year, 2 percent the second year, and 1 percent the third year.

The stemming loss on Kentucky and Tennessee fire-cured tobacco ranges from 20 to 28 percent, averaging about 24 percent. Relatively small quantities of this tobacco are stemmed as the greater part of that used in domestic manufacture is in snuff and practically none of that exported is stemmed prior to export.

## HENDERSON STEMMING, TYPE 24

Henderson Stemming is also known as northern fire-cured or northern dark-fired tobacco. It is produced in Webster, Hopkins, McLean, Union, and Henderson Counties of Kentucky, which are just north of the district in which type 22 is grown. It is marketed at Henderson and Madisonville, Ky. The annual production ranges from $3,000,000$ to $10,000,000$ pounds.

The harvesting and curing methods are the same as for types 22 and 23 except that the fires are not kept burning in the curing barns for quite so long a period. The tobacco of this type in the Madisonville locality is somewhat larger and coarser than the fire-cured tobacco of the eastern and western districts. In the territory nearer Henderson the same varieties or strains of seed are used for the production of this type as for the air-cured type called Green River. In fact, in some years many of the farmers of this district air-cure their tobacco, whereas in other years they fire-cure it. The practice in this respect is dependent largely upon weather conditions and upon the prices being paid respectively for fire-cured and dark air-cured tobacco. A large percentage of Henderson Stemming was formerly exported, and as most of it went to the United Kingdom it was usually stemmed and shipped in strip form. At present, a smaller percentage is exported and very little is stemmed before being packed.

The auction-sales marketing system prevails in this territory. The markets open about the middle of December and the selling season lasts until about the middle of March. In former years when the greater part was stemmed, practically all the strips were air-dried. At present, most of it is put through redrying machines. The loss in weight from dirt and sand shaken off in handling averages about 1 percent. The loss in weight through redrying, including the dirt and sand loss, averages about 10 percent for domestic order and about 14 per-
cent for export order. Storage losses run somewhat lower than for types 22 and 23, and somewhat higher than for Virginia fire-cured. The average loss the first year in storage runs about 3 percent, the second year about 1.5 percent, and the third year about 1 percent. The loss in stemming ranges from 20 to 28 percent and averages about 24 percent.

## BURLEY, TYPE 31

Burley tobacco is produced principally in Kentucky, southern Ohio and Indiana, western West Virginia, central and eastern Tennessee, western Virginia and North Carolina, and sections of Misssouri and Kansas. In point of production Burley ranks next to flue-cured, usually comprising from 20 to 25 percent of the total United States crop of all types. Less than 5 percent of the Burley crop is exported. Most of it is used in this country in cigarettes, and in smoking and chewing tobacco.

Burley tobacco is a light air-cured type ranging in color from a light straw to a dark tan or light brown. All Burley is harvested by the stalk-cutting method. The stalks are split by some growers, and others spear them on to sticks about $4 \frac{1}{2}$ feet long which are hung in tiers in ventilated barns or sheds. The green tobacco is permitted to dry out or cure under natural atmospheric conditions. No heat is used, except during wet weather when it is sometimes necessary to use charcoal braziers under the tobacco to prevent house burn. House burn is a fungus or bacterial disease that develops during rainy seasons, especially if the tobacco is crowded so closely in the curing barn that free circulation of air is prevented.

Burley is usually harvested during the latter part of August or first of September, and hangs in the curing barn from 6 to 10 weeks. After it is fully cured and when the tobacco is in order it is taken down and the leaves are removed or stripped from the stalks.

As a rule the Burley growers sort the tobacco into six natural groups as they strip it. The leaves that grow nearest the ground are known as spods or flyings; the next leaves upward on the plant are called trashes; next above these are the lugs; then come the bright leaf or cutter grades; next the red-leaf or heavy-leaf grades; and last the tips. In sorting out a crop it is sometimes necessary to make subdivisions of these major groups on the basis of color or length.

The auction-sales system of marketing prevails throughout the major part of the Burley territory. The markets usually open early in December or late in November and continue through the greater part of February. The peak in sales is probably reached in January. Redrying plants are located in most of the principal markets, and the tobacco is put through machines in the same way as fluecured tobacco. In some of the outlying territories and smaller markets the tobacco is air-dried. In air-drying, the hands of tobacco are hung on sticks in much the same way as the green plants. The tobacco is hung in tiers and left throughout the winter. During the winter months it loses practically all its moisture content and becomes almost bone dry. In the spring during a damp season when the tobacco absorbs sufficient moisture for handling, it is taken down and packed into hogsheads.

The loss in weight in redrying Burley tobacco, including the dirt and sand loss of 1 percent, is about the same as that of flue-cured-

10 percent for that packed in domestic order and about 11 percent for that packed in export order. The loss in weight in air-drying is slightly lower than the redrying loss, usually averaging about 9 percent, but the handling losses are perhaps slightly higher, making the total loss about the same.

Burley is packed in hogsheads 48 inches in diameter and 54 inches in height or depth. The average net weight of the hogshead is approximately 1,100 pounds. The loss in storage on Burley averages 2 percent the first year, 1 percent the second year, and 1 percent the third year. The average loss in stemming is 26 percent, with a range from about 22 to 28 percent. This range in stemming loss is due chiefly to the fact that for some products only a small portion of the stem is removed and for other products a greater part is removed.

## SOUTHERN MARYLAND, TYPE 32

Maryland tobacco is a light air-cured type similar to Burley in appearance. It is produced in five counties of southern MarylandPrince Georges, Anne Arundel, Calvert, Charles, and St. Marys. A small quantity of tobacco is produced in Frederick and Montgomery Counties but this is known as upper-country tobacco and is classified as miscellaneous domestic. Production of Maryland tobacco usually totals around $25,000,000$ pounds. For the period of 1925-34 an average of about 50 percent of the total Maryland tobacco produced was exported, but during recent years exports have declined considerably. Maryland tobacco is used by domestic manufacturers principally in the manufacture of cigarettes, blended with other cigarette types such as flue-cured and Burley.

The harvesting and curing methods of Maryland tobacco are practically the same as those practiced in the Burley territory; that is, the tobacco is stalk-cut and air-cured, but in harvesting no stalk-splitting is practiced. The handling and marketing methods in Maryland, however, are entirely different. The Maryland growers sort their tobacco into four major groups. The lower leaves that drop from the plants and are picked up in the fields and the trashy leaves on the bottom of the stalk after curing are classed together and are known as ground leaves. The next leaves above these are sorted and tied separately and known as seconds. The other leaves of the plant are sorted on the basis of body and color, the heavy darker leaves being known as dull crop and the thin bright leaves as bright crop.

Maryland tobacco is packed into hogsheads by the growers after it has remained on the farm during the winter and following spring. No air-drying nor redrying is done by the trade as it is practically air-dried on the farm. The hogsheads used are much smaller than those used in any other section. They vary in size, ranging from around 400 to 800 pounds in weight. The usual weight is about 650 pounds net.

Although the Maryland tobacco market in Baltimore operates the year round, most of the sales are made in June, July, and August. The marketing system is unique. It is the only closed-bid hogshead auction market in this country. There are two warehouses in Baltimore for handling the Maryland tobacco; one is operated by the State of Maryland and the other by the Baltimore \& Ohio Railroad. The Maryland growers ship their hogsheads of tobacco to one of these warehouses consigned to a commission merchant or to the Maryland

Tobacco Growers' Association which, in conducting sales, operates in a manner similar to a commission merchant. The growers are given free storage for as long a period as they wish and the buyers are given 6 months of free storage.

After the hogsheads have been in the warehouse for 2 weeks they are opened and the hogshead is removed from the packed and prized tobacco. An official sampler draws several hands of tobacco from six different points in the hogshead. From these draws, a six-hand representative sample is made and sealed with the official State or the railroad company's seal. This official sample is turned over to the commission merchant to whom it is consigned, or to the association. The tag on the sample bears the name of the grower, the hogshead number, and the weight.

Each day the commission merchants and the association place on display a lot of samples and a list is made up of the numbers on each sample. Every buyer is given a copy of this list. They draw lots as to their order in examining the samples. After a buyer has reviewed the samples he places his bid opposite the number of all samples on which he wishes to make an offer and drops this list in a locked box as he leaves the sample room. Every day at $1 \mathrm{p} . \mathrm{m}$. this box is opened. In each instance the highest bidder gets the hogshead if, in the opinion of the commission merchant, the price is high enough. If the high bid is rejected twice the sample is withdrawn and sales are made by private bargain. The farmers pay a fee of $\$ 2$ per hogshead to the commission merchants and the buyers pay a fee of $\$ 3$ per hogshead to the warehouse for handling charges.

No records are available of the loss in weight of Maryland tobacco between the time it is cured and the time it is inspected and sampled at storage in Baltimore. The loss in storage is higher than for Burley tobacio as no redrying is done and Maryland tobacco is packed in somewhat higher order. The average loss during the first year is 4 percent, during the second year 2 percent, and during the third year 1 percent. The average loss in stemming Maryland tobacco is the same as for Burley, namely 26 percent.

ONE SUCKER, TYPE 35
One Sucker tobacco, a dark air-cured type, is produced in northcentral Tennessee and south-central Kentucky. The markets are Franklin, Scottsville, and Russellville, Ky., and Westmoreland, Tenn. Production of this type is usually around 2 percent of the total United States tobacco crop.

One Sucker derives its name from a tendency of the plant to produce only one crop of suckers after topping. The harvesting method is the same as for fire-cured tobacco, that is, it is stalk-cut. The color range is also similar to fire-cured with perhaps slightly more light-brown tobacco in the crop. It is cured under natural atmospheric conditions. It is characterized by a long narrow leaf, a rather large coarse stem, and cross fibers at an acute angle to the stem.

About 30 percent is exported and 70 percent used domestically. The principal domestic use is for plug and twist chewing tobacco, mostly twist. Considerable quantities go into export trade in the form of Black Fat. In some instances One Sucker is packed straight for Black Fat trade and in others it is mixed with fire-cured tobacco of similar appearance. Black Fat is a trade term applied to tobacco
packed especially for the African and South Sea Islands trade. The tobacco is almost saturated with mineral oil, petrolatum, or other prepared sauces and then packed in tierces or boxes and subjected to tremendous pressure.

About 80 percent of the total One Sucker that is exported goes out in the form of Black Fat; the 20 percent remainder consists of lowgrade lugs and trash. The One Sucker used by domestic manufacturers is packed in hogsheads 54 inches in depth and 46,47 , or 48 inches in diameter, ranging from 1,000 to 1,250 pounds net weight, and averaging about 1,100 pounds.

One Sucker is sold at auction orer loose-leaf floors. In handling orer the floors, a certain amount of sorting is done on the basis of quality, color, and length as the tobacco is unloaded from the farmers' wagons or trucks and placed on the baskets. The markets for One Sucker usually open in about the second week in December and sales continue until the latter part of March.

The moisture content of One Sucker at the time of delivery by the farmers and the keeping quality of the tobacco prohibit packing without reordering. About 85 percent is air-dried before packing in hogsheads and the other 15 percent is shipped to some point where it can be put through a redrying machine. The air-dried One Sucker is packed with a moisture content of about 14 percent, the machinedried with slightly less. The loss in weight from handling, ordering, and packing, including a dirt and sand loss of about 1 percent, ranges from 8 to 12 percent, areraging about 9 percent. The packers of Black Fat show no loss in the operation. They have an actual weight gain due to the addition of oil, etc. The loss in weight in storage arerages about 2 percent the first year, 1.5 percent the second year, and 1 percent the third year.

Because of the long narrow leaf and the coarse stem and the purposes for which used, the percentage of loss in stemming One Sucker is higher than for most other types, ranging from 25 to 35 percent, and averaging about 30 percent.

Green River tobacco is produced in the northern part of Kentucky in the territory adjacent to Owensboro and Henderson, and is marketed at these two points. Production of this type in former years was as high as $60,000,000$ pounds, but in recent years has ranged from $10,000,000$ to $20,000,000$ pounds. It is a dark air-cured type, ranging in color from a light tan to a rery dark brown. The variety or strain of seed used is the same as for type 24. Growers in this district either air-cure this tobacco and sell it as Green River, or fire-cure it and sell it as Henderson Stemming.

Green River tobacco is harrested by the stalk-cutting method. It is air-cured, sold at auction, and packed in hogsheads areraging about 1,400 pounds in weight. The marketing period is from early in December until early in March. As is the case with most of the southern types, there is some rariation from year to year, in the opening and closing dates of the markets. Late plantings and consequent late harresting and curing may delay the opening dates. Weather conditions unfarorable to stripping, sorting, and handling by the farmers may delay the closing dates.

Green River tobacco is used in the manufacture of chewing tobacco, snuff, and smoking tobacco. At one time a considerable quantity was exported, but more recently exports have declined somewhat.

Practically all of this tobacco is redried. The loss in weight in redrying, including a dirt and sand loss of 1 percent, averages about 10 percent for domestic trade and about 14 percent for export trade. The loss in weight in storage averages about 3 percent the first year, 1.5 percent the second year, and 1 percent the third year. The loss in stemming ranges from about 20 to 28 percent and averages about 24 percent.

## VIRGINIA SUN-CURED, TYPE 37

Virginia sun-cured tobacco is produced in a limited district near Richmond, Va., and practically all of it is marketed at that point. The annual production during the last 10 years has averaged about $4,000,000$ pounds.

Virginia sun-cured tobacco derives its name from the former practice of hanging the green tobacco on scaffolds in the fields during the greater portion of the curing process. It is really an air-cured type of tobacco, very dark in color. Practically all is used in the domestic manufacture of chewing tobacco; very little is exported.

Virginia sun-cured tobacco is marketed under the loose-leaf auctionsales system. The market usually opens about the middle of November and extends until the latter part of February or the first of March. The tobacco is redried, and is packed in hogsheads about the same size as those used for the flue-cured and fire-cured tobacco produced in Virginia. The average net weight of a hogshead is approximately 1,250 pounds. The average loss in weight in redrying, including a dirt and sand loss of 1 percent, is about 11 percent. The average loss in storage the first year is 1 percent, the second year 1 percent, and the third year 0.5 percent. The average loss in stemming is about 24 percent.

## PENNSYLVANIA SEEDLEAF, TYPE 41

Pennsylvania Seedleaf tobacco, also known as Pennsylvania Broadleaf, Pennsylvania Filler, and Lancaster and York County Filler, is produced principally in Lancaster and adjoining counties of Pennsylvania.

The annual production during the last 10 years has areraged about $43,000,000$ pounds. This type is used principally for cigar fillers. A limited quantity of the thinner, lighter bodied leaves, which are free of injury, are selected and used as binders or as stogie wrappers. The regular filler grades are known locally as wrappers, but are used only for cigar fillers. The lower or stemming grades are known locally as fillers and are used principally in the manufacture of scrap chewing tobacco or in shredded fillers for low-priced cigars. A rery limited quantity is exported.

Pennsylvania Seedleaf is harvested by the stalk-cutting method and like all cigar-leaf tobacco, it is air-cured. After the tobacco is fully cured it is stripped from the stalk and tied into hands of 14 to 18 leaves, The hands are then put up in paper-wrapped bundles or bales weighing from 50 to 70 pounds for delivery to packers.

Pennsylvania Seedleaf is usually sold while still hanging in the curing shed. Independent dealers, and buyers who represent the larger cigar manufacturers, visit the premises of the growers and purchase the tobacco. Each requires that the crop be delivered to the buyer's ware-
house as soon as stripped and baled. The contract specifies prices for wrappers and for fillers and usually stipulates that the tobacco shall be free from damage when delivered. Occasionally the tobacco is not sold until after it is baled. Pennsylvania Seedleaf is usually delivered by the growers to the packers in the period from January 1 to March 31. The bulk of the delivery is made in January and February.

Some growers pack their tobacco in cases, or engage some packer to do it for them at specified rates per pound. The cases are stored to undergo the sweating process. Other growers have organized and operate cooperative packing plants, but most of the Pennsylvania Seedleaf is marketed by the direct-sales method and is delivered to the buyers in bundle form. The majority of the growers seem to prefer selling their tobacco before the heary loss in packing and sweating.

Pennsylvania Seedleaf is a very dark, heavy-bodied, and rather large and coarse type as compared with other cigar-leaf types, but its general texture, flavor, and aroma are such that it is well adapted for use as cigar fillers. It will carry a relatively high percentage of moisture without molding or damaging in the bulk or case. At the time it is delivered by the growers the moisture content usually ranges from 18 to 32 percent. Tests made by the Department of Agriculture show that Pennsylvania Seedleaf should be packed in cases with an average moisture content of about 25 percent. If it is packed with less than 24 percent of moisture it may not sweat properly. If it is packed with more than 26 percent of moisture it is subject to loss from black rot and mold. ${ }^{5}$

Some packers of Pennsylvania Seedleaf practice bulk-sweating prior to packing in cases. When it is handled in this way the initial handling loss, including dirt and sand, breakage, and moisture loss, ranges from 3 to 5 percent and the average loss is about 4 percent. When the tobacco is bulk-sweated the loss in the period from packed weight to sampling weight is somewhat less than that on tobacco packed direct into cases. The loss in weight from packed weight to sampling weight ranges from 8 to 12 percent, averaging about 11.3 percent.

Other packers of Pennsylvania Seedleaf pack direct into cases without bulk-sweating. When packed without bulk-sweating the handling loss due to dirt and sand, breakage, and possibly some moisture loss, ranges from 2 to 3 percent. The loss during the period from packed weight to sampling weight, which is principally a moisture loss, ranges from 8 to 14 percent. The average loss during this period is about 12.1 percent. Packing is usually completed in May and the sampling is done the following fall after the tobacco has gone through the first summer sweat. The first sweat is the hardest and results in greater loss than occurs in any subsequent sweat.

By the end of the first year after sampling, this tobacco usually loses an additional 2.3 percent, by the end of the second year another 2.4 percent, and at the end of the third year an additional 1.7 percent.

In case-sweating, the tobacco is packed in substantial wooden cases all 30 by 30 inches across the ends or heads, and ranging in length from 36 to 52 inches. The average length of a case is about 42 inches. The weight of cases when packed ranges from 250 to 365 pounds net, or from 325 to 450 pounds gross. These cases have $1 / 2$-inch spaces between the end boards in order to allow ventilation and the escape of surplus moisture during sweating. The inside of the case, except

[^5]the ends, is covered with heavy paper. The tobacco is packed lengthwise in the case with the butts of the hands outward toward the end and the tails slightly lapping in the center. It is packed several inches above the top of the case; then a frame is placed on it and it is put under a casing press and the tobacco is pressed down until the lid or top of the case can be nailed on. Each case is marked with the net weight and gross weight. The cases are then stored in rows 5 to 20 cases high in warehouses especially built for tobacco storage and sweating. Some of these warehouses have heating equipment and the sweating is speeded up through the application of artificial heat.

Tobacco of the regular cigar-filler grades of Pennsylvania Seedleafcalled wrappers by the growers-are usually stemmed just before the time they enter into the manufacturing process. Tobacco of the lower grades-called fillers by the growers-is often stemmed months in advance of use in manufactured products. The scrap chewing manufacturers as a rule place the strips, or stemmed tobacco, in a bulk and put it through an additional sweating process. The manufacturers of prepared short fillers, or "grinders" as they are known in the trade, use a considerable quantity of the stemming grades or X group tobacco. This is put through stemming machines, is dried, stored in bins, and sold to manufacturers of short-filler cigars. The average stemming loss on all grades of Pennsylvania Seedleaf is about 28 percent. The stemming loss ranges from about 26 to 30 percent.

## OHIO, TYPES 42-44

Three types of cigar-filler tobacco are produced in the southwestern section of Ohio, mostly in Darke, Preble, Butler, Miami, Montgomery, and Warren Counties. Type 42 is known as Gebhardt; type 43, as Zimmer or Zimmer Spanish; and type 44, as Dutch or Little Dutch.

In recent years the annual production of the three types has averaged about $24,000,000$ pounds. No official estimates are made of the production of each type separately, but on the basis of average stocks held by dealers and manufacturers on July 1 of each year since 1929, the production averages about 37 percent of Gebhardt, 47 percent of Zimmer, and 16 percent of Dutch.

The general harvesting, curing, marketing, and handling methods are so similar that in considering losses in weight the three types may be discussed under one heading. These tobaccos are stalk-cut, aircured, and marketed under the country-sales system. The buying is done in the fall of the year and deliveries are usually made from January to April. Sometimes the movement of the crop from growers' hands into buyers' hands is much later and extends into the second quarter of the year.

Most of the buyers and packers are located in Dayton, but some are located in small towns throughout the producing district, and some of the Dayton buyers have packing houses at outlying points. The growers sort their crop into two major grades locally known as wrappers and fillers. The so-called wrappers are the actual cigarfiller grades. The so-called filler grades are suitable for use in scrap chewing tobacco and are sometimes stemmed and shredded foruse as short fillers in low-priced cigars. The growers deliver these tobaccos, packed in cases, to the buyers who usually repack and resort, separating badly broken, inferior, and damaged leaves. Some buyers practice bulk-sweating; others case-sweat only. Gebhardt and Zim-
mer tobaccos usually go through one spring-and-summer natural sweat and are then taken out of the cases, in the fall, dipped in water, and force-sweated. This is known as resweating. Dutch tobacco is seldom dipped and resweated.

The initial loss in handling and packing these types ranges from a little more than 3 percent to a little more than 4 percent. The loss in sweating and resweating ranges from about $10 \frac{1}{2}$ to 12 percent. The handling and storage loss on type 44 is somewhat lower than the loss on types 42 and 43 because it is not resweated. These types lose between 2 and 3 percent each year while in storage up to the third year. The loss in stemming Gebhardt averages about 27 percent; in stemming Zimmer about 28 percent; and in stemming Dutch about 30 percent. The higher stemming loss in Dutch may be attributed to the narrow, stringy leaves and the consequent larger proportion of stem to leaf surface.

## GEORGIA AND FLORIDA SUN-GROWN, TYPE 45

Georgia and Florida sun-grown tobacco is produced in north-central Florida and southern Georgia. The principal marketing point is Quincy, Fla. Production during the last 5 years has ranged from approximately $1,200,000$ pounds to less than 100,000 pounds, averaging around 600,000 pounds annually. This is a cigar-filler type of tobacco, but the leaves are smaller and of finer texture than those of other filler types produced in this country, usually ranging in length from 8 to 14 inches. In general appearance it is similar to Puerto Rican tobacco.

Georgia and Florida sun-grown tobacco is primed and cured in barns under natural atmospheric conditions except that during damp seasons charcoal or coke braziers are sometimes used to prevent pole sweat or house burn. The greater part is grown under contract with buyers, but some is sold by private sale on the farm of the grower. After the tobacco is cured it is tied into hands and delivered to the packing house either in paper-wrapped bundles or in boxes.

Deliveries are usually made in June and July, with the bulk of the crop moving in July. The packers untie the hands and pile the leaves into large bulks ranging from 20,000 to 40,000 pounds each. As with most filler types, a hard sweat is required; therefore the leaves are often sprayed with water when the bulks are turned ${ }^{6}$ in order to force the fermentation. This causes the tobacco to become dark but does not detract from its value. When handled in this way the temperature of the bulk during fermentation often goes as high as $150^{\circ} \mathrm{F}$.

After the fermentation has been completed the leaves are stemmed, and as the stemming process requires that the leaves be very soft and pliable, the moisture content is too high for immediate packaging. The strips, or stemmed tobacco, are dried out until the moisture content is reduced to about 15 percent. The tobacco is then packed in bales averaging about 160 pounds in weight.

The greater part of the loss in weight in handling Georgia and Florida sun-grown tobacco occurs before packing and averages about 17.5 percent. Subsequent losses average about 2 percent for each year that the tobacco is held in storage. The loss in stemming averages about 21.5 percent.

[^6]
## PUERTO RICAN, TYPE 46

Puerto Rican cigar-leaf tobacco is produced in the central and inland portion of Puerto Rico. It is marketed and handled at a number of points on the island. The principal markets are Caguas, Juncos, Cayey, Comerio, San Lorenzo, and Utuado. The arerage annual production for the last 5 years has been about $21,000,000$ pounds.

Puerto Rican tobacco is used principally for cigar fillers and the major portion of it is used in continental Linited States. The leaves are smaller and thinner bodied than most of the cigar-filler trpes produced in the United States. It is aromatic and has a distinctive flavor that blends well with other filler types.

It is harvested by both the stalk-cutting and the priming methods. It is air-cured under natural atmospheric conditions in curing barns that may be either of wood construction or constructed of poles thatched with cane or palm leaves.

Tobacco is grown and marketed in Puerto Rico principally under a system called "refractioning." The growers are supplied by dealers and merchants with food, fertilizer, and other necessities, and are obligated to deliver and sell their tobacco to them. The tobacco is delivered by the growers in large bundles or lots rolled in burlap or cloth. It is usually marketed between April 1 and July 1, although some may be delivered as early as March. A limited amount of sorting is done by the growers based on the position of the leares on the plant and on the general quality. The subdirisions that are made are known by such Spanish terms as Coronas, Resagos, Boliches, etc. If the tobacco is refractioned through a general merchant it is again sold to a regular packer. In the packing houses finer lines of distinction are drawn as to quality or grade.

Some bulk fermentation is practiced before the remoral of the stems, and some fermentation occurs after stemming. The stemmed leaf is carefully sorted and graded on the basis of quality, length, and, to a certain extent, color. About 30 percent of the Puerto Rican tobacco is packed in barrels for storage and shipment. The remainder is packed in bales. The size of the bales is approximately 34 by 28 by 30 inches, and the arerage net weight is approximately 150 pounds.

The loss in weight in handling and packing Puerto Rican tobacco arerages about 12 percent. The loss in the first year after packing, during which time the first and hardest sweat occurs, arerages about 5 percent. The loss in storage during the second year arerages about 2 percent. The loss in stemming averages about 21.5 percent.

## CONNECTICUT BROADLEAF, TYPE 51

Connecticut Broadleaf tobacco is produced in the raller of the Connecticut River from near the Massachusetts State line to Glastonbury, Conn., principally on the east side of the river. Some is handled and packed at rarious points throughout the valley but Hartford, Conn., is the principal marketing point. The annual production for the last 10 years has areraged about $15,000,000$ pounds. It is used principally for cigar binders, but about 15 or 20 percent is used for wrappers and a small quantity of the lower grades is used in scrap chewing.

The leaves are relatively large, ranging in length from about 18 to 24 inches. They are smooth and of good texture, and are brown in color.

Connecticut Broadleaf is harvested by the stalk-cutting method and is air-cured in barns under natural atmospheric conditions. After the tobacco is fully cured and is in good order for handling, it is taken down and the leaves are stripped from the stalks. It is marketed under a country-sales system, the buyers visiting the farms of the growers and bargaining as to price. From 50 to 60 percent of the growers sort their own tobacco after it is stripped from the stalks. Otherwise the sorting is done in the packing houses of the dealers. It is sorted into 10 to 12 grades, the major groups of grades being known as wrappers, seconds, top leaves, fillers, and stemming. Usually there are several grades of wrappers and seconds. For delivery by growers, the tobacco, whether sorted or not, usually is packed in paper-wrapped bundles weighing from 30 to 60 pounds. Some growers who sort their own tobacco also pack it in cases before delivery. It is delivered by the growers to the dealers from January to May; the peak of the deliveries comes in February. Usually most of the crop is marketed during the first quarter of the year.

Connecticut Broadleaf is not bulk-sweated but is sometimes repacked into bundles for sweating. Usually it is packed directly into cases and put into a sweating room with a temperature of from $85^{\circ}$ to $95^{\circ} \mathrm{F}$. for a period of 6 to 8 weeks. About 30 percent is packed in cases for natural sweat; that is, it is stored in a warehouse with no temperature control.

The moisture content ranges from 25 to 30 percent at the time of delivery. The loss in handling and packing ranges from 2 to 5 percent. The loss in weight during the period of the first sweat, or from the time it is packed until the following fall when it is sampled, averages about 10 percent. From sampling time to the following fall the loss ranges from 2 to 3 percent, averaging about 2.5 percent. If held longer than 2 years there is an additional loss of about 2.5 percent the third year. The stemming loss averages about 22.5 percent.

## CONNECTICUT HAVANA SEED, TYPE 52

Connecticut Havana Seed tobacco is produced in the same territory as Connecticut Broadleaf, and from Greenfield, Mass., to Middletown, Conn. Some is grown in the Housatonic Valley. Hartford is the principal market. The average annual production for 1926 to 1932 was about $17,000,000$ pounds. Production declined to about $10,000,000$ pounds in $1933,5,500,000$ pounds in 1934, and $6,000,000$ pounds in 1935. It is used principally for cigar binders. Although about the same percentage of Havana Seed as Broadleaf is classified as wrappers by the packers, the percentage actually used for wrapper purposes is not as large. The tobacco of the lower grades is used in scrap chewing. This type as a whole is somewhat thinner bodied than Broadleaf, is very smooth and of fine texture, and runs lighter in color.

In former years part of the Havana Seed crop was primed, but recently practically all of it has been stalk-cut. It is air-cured in barns under natural atmospheric conditions. The marketing system and method of delivery are the same as for Broadleaf except that a very large percentage is sold by the growers in unassorted bundles and
then sorted by the packers. It is also sized to 2 -inch lengths ranging from 14 to 26 inches, the greater part ranging from 18 to 24 inches. Deliveries are made by the growers from December to March, in some years extending into April. Most of the deliveries are usually made in January.

The packing and fermentation methods employed are similar to those used in handling Broadleaf. The initial handling and packing loss ranges from 3 to 6 percent, averaging slightly higher than the initial loss in handling Broadleaf. The average loss during the period of the first sweat from packing time to sampling time is about 10 percent. The average loss during the second year is about 2.5 percent, and during the third about 2 percent. The average loss in stemming is 23 percent.

## NEW YORK AND PENNSYLVANIA HAVANA SEED, TYPE 53

New York and Pennsylvania Havana Seed tobacco is produced in a widely scattered area through northern Pennsylvania and southern and central New York. The principal marketing points are Elmira and Syracuse, N. Y. The average annual production for the last 10 years has been about $1,500,000$ pounds. The tobacco of this section has been classified' as a binder type, but from a type standpoint two kinds are produced. The Big Flats is a binder type similar to the Connecticut Havana Seed, and the Onondaga is more of a filler type. At one time these tobaccos were used principally for cigar binders and fillers, but more recently the greater part of them has been used in scrap chewing tobacco.

Type 53 tobacco is stalk-cut and is air-cured in barns under natural atmospheric conditions. It is sold mostly at the farms of the growers by private sale, and delivered to the dealers in paper-wrapped bundles ranging in weight from 30 to 50 pounds. Little sorting is done by the growers. They usually sort into only two grades. The dealers and packers sort out the binders and fillers from the best of the growers' grades and pack them in cases. Some bulk-sweating is practiced but most of the better quality tobacco is packed direct into cases and is "natural sweated." The stemming grades are usually sweated in the paper-wrapped bundles in which they are delivered by the growers. Deliveries are usually made in the first quarter of the year, and most of the packing is done within this period.

The initial loss in handling and packing the better grades, which are packed direct into cases, a ererages about 2.5 percent, and the loss from packing time to sampling time in the fall ranges from 8 to 12 percent, averaging about 10 percent. On that part of the tobacco which is bulk-sweated before packing the initial loss ranges from 5 to 7 percent, but there is a decrease in the loss during the period of the first sweat from packing to sampling time. This loss will average about 6.5 percent. Regardless of the method of handling, the loss up to sampling time is practically the same, averaging about 12.5 percent. The loss in storage from sampling time to the next fall averages about 3 percent. If held another year there is an additional loss of about 1.5 percent. The average loss in stemming is about 26.5 percent. This is slightly higher than for most other cigar-leaf types, because such a large percentage of this tobacco is used for scrap chewing. In stemming tobacco for scrap chewing purposes the stem must be completely removed.

## SOUTHERN AND NORTHERN WISCONSIN, TYPES 54 AND 55

Southern Wisconsin tobacco, type 54, is produced in south-central Tisconsin. Edgerton and Janesville are two of the principal markets. Northern Wisconsin, type 55, is produced in west-central Wisconsin and east-central Minnesota. Viroqua and Chippewa Falls are two of the principal markets. Although these two types are very similar in general appearance and some grades are exactly comparable, a distinction is made in the trade on the basis of general quality. For the last 5 rears the arerage annual production of southern Wisconsin tobacco has been about $16,500,000$ pounds, and of northern Wisconsin tobacco about $10,000,000$ pounds. Although more than 60 percent of these types is used for scrap chewing purposes, they are classified as cigar-binder types. A much larger percentage of northern than of southern Wisconsin tobacco is selected and used for binder purposes.

Considering the types as a whole, the leaves of Wisconsin tobacco are somewhat larger and coarser than of the binder types produced in Connecticut. Wisconsin tobacco is stalk-cut and air-cured. It is marketed by private sale at the farm of the grower or through a growers' cooperative organization. These types are usually marketed during the first quarter of the year. As a rule, the greater part of the crop is out of the growers' hands by the 1st of April but sometimes, because of adverse weather, the marketing period extends into the second quarter. Only a limited amount of sorting is done by the growers prior to delivery. They sort into two grades known as wrappers and fillers. The so-called filler grades, usually known in the trade as stemming, are used principally for scrap chewing. The tobacco is delivered in paper-wrapped bundles ranging in weight from 40 to 50 pounds.

The packers sort and size the so-called wrapper grades and from these select the leaves of binder quality. Most of the Wisconsin binder grades are packed direct into cases after being sorted and sized, but some are bulk-sweated for about 2 weeks before packing. The initial loss in handling the better grades when the tobacco is bulk-sweated ranges from 6 to 10 percent, averaging about 8 percent. On such bulk-sweated tobacco the loss in weight during the first sweat, after it is packed in cases until the following fall, a rerages about 7 percent. When packed direct into cases without bulk-sweating the initial loss in handling and packing averages about 3 percent, but the loss during the first sweat is much higher, ranging from 10 to 15 percent, and areraging about 13 percent. The subsequent losses in storage during the second and third years are about 2 and 1.5 percent, respectively, regardless of whether the tobacco is bulk-sweated or packed direct into cases.

The stemming grades of Wisconsin tobacco are usually bulksweated for about a year in the paper-wrapped bundles in which they are delivered by the growers. Just before being stemmed the tobacco is taken out of the bundles, the damaged tobacco is thrown out, moisture is added, and it is rebulked and resweated for a short period. The net yield on the stemming grades is somewhat lower than the net yield on binder grades because of difference in the sweating processes, and because more damage occurs from black rot and mold. It is difficult to determine the losses in the progressive steps of handling, but the total loss averages nearly 20 percent. The
average stemming loss for southern Wisconsin tobacco is about 23 percent and for northern Wisconsin about 25 percent.

## CONNECTICUT SHADE-GROWN, TYPE 61, AND GEORGIA AND FLORIDA SHADE-GROWN, TYPE 62

As the two types of shade-grown tobacco are very similar in regard to the cultural and handling methods and as the losses in weight in handling are comparable, they will be considered together. Connecticut shade-grown is produced in the valley of the Connecticut River in Massachusetts and Connecticut. The principal marketing point is Hartford, Comn. The arerage annual production for the last 5 years has been about $5,000,000$ pounds. Georgia and Florida shade-grown is produced in north-central Florida and southern Georgia. The principal marketing point is Quincy, Fla. The average annual production for the last 5 years has been about $2,000,000$ pounds.

Shade-grown tobacco is used principally for cigar wrappers. The leares are small, usually ranging in length from 10 to 16 inches, although some leares are as short as 8 inches and some as long as 20 inches.

Body, texture, elasticity; combustibility, and color are the most important elements of quality in tobacco for cigar wrappers. Shadegrown tobacco is very thin and tissuey, is of very fine texture, is elastic, and ranges in color from light tan to light brown. It is essential that cigar wrappers burn well and evenly, and that the leares are free of injury. The greatest care must be exercised by the growers throughout the culture and handling in order to produce tobacco of such quality. Production costs are higher for shade-grown than for any other types. It differs from all other types in that it is produced under artificial shade. Three kinds of shade are used-slats, cloth, and a combination of slats and cloth. In recent years the use of cloth has predominated.

Shade-grown tobacco is harvested by priming or picking the leaves as they ripen, beginning at the bottom of the stalk and removing two or three leaves at a time. Each priming is handled separately and the leaves are carefully carried to the curing barns. When they have wilted sufficiently to permit handling without breakage, they are strung beadlike on twine by punching a hole through the butt of the stem. About 30 leares are placed on each string, face to face and back to back. Each end of the string is fastened to a lath and the laths are hung in the tiers of the curing barn.

The tobacco is watched closely during the curing process and through a system of regulated and controlled rentilation, temperature and humidity are kept at the desired point. The procedure followed is governed by weather conditions.

After the tobacco is thoroughly cured the strings are cut loose from the ends of the laths, the leares are drawn together in the center of the strings, and the free ends of the strings are tied around the butts of the leaves, thus forming hands of about 30 leaves each. These bands are packed in boxes for delivery to the packing houses.

In both Connecticut and Florida the marketing system for shadegrown tobacco differs from that of other cigar-leaf types. In practically all cases the packers and dealers are also growers. In addition to handling their own tobacco, they handle some for other
growers on a contract basis specifying prices. Some is raised for them by sharecroppers, and some is handled, packed, and sold for other growers on a commission basis. Connecticut shade-grown is delivered to the packing houses in August, September, and October, the greater part of the crop usually being delivered before October 1. Georgia and Florida shade-grown is delivered in July, August, and September, practically all deliveries being completed prior to October 1.

When shade-grown tobacco arrives at the packing house it is removed from the boxes and placed in bulks about 5 or 6 feet wide and from 12 to 16 feet long, and usually about 8 feet high. These bulks contain from 4,000 to 6,000 pounds. Temperature and humidity are definitely controlled in the bulking room. A temperature of $75^{\circ}$ to $85^{\circ} \mathrm{F}$. is usually maintained and the relative humidity is not

Figure 8.-Stenciling United States Department of Agriculture inspection seal and certificate numbers on bales of Connecticut shade-grown tobacco.
allowed to fall below 70 percent. A perforated metal tube is placed through the center of each bulk for the purpose of inserting a thermometer for inner temperature readings.

The moisture content of the tobacco when placed in the bulks ranges from 24 to 32 percent. With this moisture content, fermentation starts at once and the temperature of the bulk gradually increases until within about a week it reaches a maximum of from $110^{\circ}$ to $120^{\circ} \mathrm{F}$. The maximum temperature attained and the number of days before a maximum is reached vary with the condition and quality of the tobacco and the room temperature. When the temperature starts downward the tobacco is turned or is rebulked. In rebulking the position of the tobacco is reversed; that is, the outer layers are placed on the inside and the inner layers on the outside of the new bulk. Fermentation starts again and the temperature again rises, but much more slowly, and it usually does not reach a
maximum of more than $105^{\circ}$ after this first rebulking. The tobacco is turned again when the maximum temperature is reached. It is always turned at least three times and sometimes as many as five rebulkings are necessary. Each time the temperature rises more slowly and a lower maximum point is reached. Sometimes 15 days elapse between turnings.

When the tobacco comes out of the bulks it is sorted, sized, tied into hands, packed loosely in cases, and is placed in a mulling room for 3 or 4 weeks where a temperature of about $90^{\circ} \mathrm{F}$. is maintained.

Shade-grown tobacco is sorted by skilled laborers on the basis of color, body, texture, uniformity, and injury, and is sized to 1 -inch lengths. It is usually sorted into 10 to 15 grades. When the sorted and sized tobacco comes out of the mulling room it is packed and pressed into bales about 32 by 32 by 12 inches, ranging in weight from 150 to 175 pounds net and averaging about 165 pounds each (fig. 8). The moisture content at the time of baling ranges from 18 to 20 percent, and as some further fermentation takes place the bales are usually placed in a warm room for 3 or 4 weeks before they go into regular storage.

The loss in handling, sorting, and packing shade-grown tobacco ranges from 9 to 11 percent, averaging about 10 percent. The loss from packing to sampling time ranges from 2 to 2.5 percent. The loss in storage from sampling time to the end of the next year ranges from 2.5 to 3 percent.

Shade-grown tobacco, as a rule, has passed into the hands of manufacturers and been used in the manufacture of cigars before it is 2 years old. If it is held longer there is an additional loss of about 2 percent the third year.

The average loss in stemming Connecticut shade-grown is about 18.5 percent and Georgia and Florida shade-grown about 17 percent.

## APPENDIX

Table 4.-Flue-cured tobacco, types 11-14: Stocks owned by dealers and manufacturers in the United States, as reported and on a converted-weight basis, semiannually 1912-16, quarterly 1917-36

${ }^{1} 1$ pound stemmed equal to 1.418 pounds unstemmed.
21 pound, unstemmed basis, equal to 1.115 pounds farm-sales weight and 0.89 pound unstemmed processing weight.
${ }^{3} 1$ pound unstemmed processing weight equal to 0.705 pound stemmed processing weight.

Table 20.-Georgia and Florida sun-grown tobacco, type 45: Stocks owned by dealers and manufacturers in the United States, as reported and on a convertedweight basis, quarterly 1929-36

${ }^{1} 1$ pound stemmed equal to 1.275 pounds unstemmed.
${ }^{2} 1$ pound, unstemmed basis, equal to 1.245 pounds farm-sales weight and 0.94 pound unstemmed processing weight.
${ }^{3} 1$ pound unstemmed processing weight equal to 0.785 pound stemmed processing weight.

Table 21.-Georgia and Florida tobacco, types 45 and 62: Stocks owned by dealers and manufacturers in the United States, as reported and on a converted-weight basis, semiannually 1912-16, quarterly 1917-36
[Beginning April 1929, factors for types 45 and 62 combined were not used; the figures are the sums of the individual types. Data for these types separately for years 1929-36 are shown in tables 20 and 30 , respectively]

## ORGANIZATION OF THE UNITED STATES DEPARTMENT OF AGRICULTURE WHEN THIS PUBLICATION WAS LAST PRINTED

This circular is a joint contribution from
Bureau of Agricultural Economics
A. G. Black, Chief.

Agricultural Adjustment Administration
H. R. Tolley, Administrator.

[^0]:    1 The authors are grateful to Alice Wolfe, Mrs. Sue Ugast, and Catherine Coleman for their assistance in preparing the manuscript and statistical tables. They also wish to express their appreciation for the wholehearted cooperation of the tobacco trade in furnishing the information which made this circular possible.

[^1]:    ${ }^{2}$ For a further discussion of harvesting, curing, and marketing methods, see the following publication: Gage, C. E. american tobacco types, uses, and markets. U. S. Dept. Agr. Cir. 249,88 pp., illus. 1933.

[^2]:    ${ }^{1}$ Losses and remainders under cleaning，handling and packing，and sweating and drying in storage are percentages of farm－sales weight．Net yield is the stemmed processing weight．
    ${ }^{2}$ Removal of sand，dirt，etc．
    ${ }^{3}$ Includes sand and dirt loss and loss of moisture from redrying or air－drying．
    ${ }^{4}$ Storage losses calculated progressively，based on packed weight，domestic order．
    ${ }^{5}$ Percentages in removal of stem or midrib are based upon weight of leaf put into stemming process irre－ spective of time of operation．
    ${ }^{6}$ Negligible．
    ${ }_{7}$ Maryland tobacco is packed in hogsheads at the farm；therefore losses prior to packing are borne by the grower．

    ## Table 2．－Cigar－leaf types of tobacco：Average percentages of loss in weight from different causes and percentages of weight remaining ${ }^{1}$

[^3]:    ${ }^{3}$ Note discussion of Black Fat in the section on One Sucker, type 35, p. 19 .

[^4]:    ${ }^{4}$ Air-drying is discussed in the section on Burley, type 31, p. 17.

[^5]:    ${ }^{5}$ Unpublished data in files of tobacco investigations, Bureau of Plant Industry, U. S. Department of Agriculture.

[^6]:    ${ }^{6}$ See discussion of turning and rebulking under section on cigar-wrapper tobacco, types 61 and $62, \mathrm{p} .29$.

[^7]:    ${ }^{1} 1$ pound stemmed equal to 1.282 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.12 pounds farm-sales weight and 0.99 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.78 pound stermed processing weight.

[^8]:    ${ }^{1} 1$ pound stemmed equal to 1.299 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.18 pounds farm -sales weight and 0.98 pound unstemmed processing weight.

[^9]:    See footnotes at end of table.

[^10]:    ${ }^{1} 1$ pound stemmed equal to 1.316 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.04 pounds farm-sales weight and 0.95 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstenmed processing weight equal to 0.76 pound stemmed processing weight.

[^11]:    11 pound stemmed equal to 1.316 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.125 pounds farm-sales weight and 0.96 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.76 pound stemmed processing weight.

[^12]:    ${ }^{1} 1$ pound stemmed equal to 1.351 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.02 pounds farm-sales weight and 0.95 pound unstemmed processing weight.
    31 pound unstemmed processing weight equal to 0.74 pound stemmed processing weight.

[^13]:    ${ }^{1} 1$ pound stemmed equal to 1.429 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.09 pounds farm-sales weight and 0.96 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.70 pound stemmed processing weight.

[^14]:    ${ }^{1} 1$ pound stemmed equal to 1.316 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.13 pounds farm-sales weight and 0.96 pound unstemmed processing weight.

    31 pound unstemmed processing weight equal to 0.76 pound stemmed processing weight.

[^15]:    11 pound stemmed equal to 1.316 pounds unstemmed
    21 pound, unstemmed basis, equal to 1.13 pounds farm-sales weight and 0.98 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.76 pound stemmed processing weight.

[^16]:    ${ }^{1} 1$ pound stemmed equal to 1.387 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.11 pounds farm-sales weight and 0.895 pound unstemmed processing weight.
    31 pound unstemmed processing weight equal to 0.72 pound stemmed processing weight.

[^17]:    See footnotes at end of table.

[^18]:    ${ }^{1} 1$ pound stemmed equal to 1.390 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.124 pounds farm-sales weight and 0.89 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.72 pound stemmed processing weight.

[^19]:    ${ }^{1} 1$ pound stemmed equal to 1.370 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.12 pounds farm-sales weight and 0.885 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.73 pound stemmed processing weight.

[^20]:    ${ }^{1} 1$ pound stemmed equal to 1.225 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.185 pounds farm-sales weight and 0.935 pound unstemmed processing weight.
    ${ }_{3} 1$ pound unstemmed processing weight equal to 0.815 pound stemmed processing weight.

[^21]:    ${ }^{1} 1$ pound stemmed equal to 1.275 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.17 pounds farm-sales weight and 0.96 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.785 pound stemmed processing weight.
    ${ }^{4}$ Beginning Jan. 1, 1936, stocks on the island of Puerto Rico were reported, but these stocks are not included in the 1936 figures in this table.

[^22]:    ${ }^{1} 1$ pound stemmed equal to 1.292 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.07 pounds farm-sales weight and 0.87 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.775 pound stemmed processing weight.

[^23]:    ${ }^{1} 1$ pound stemmed equal to 1.299 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.07 pounds farm-sales weight and 0.87 pound unstemmed processing weight.
    ${ }_{3} 1$ pound unstemmed processing weight equal to 0.77 pound stemmed processing weight.

[^24]:    See footnotes at end of table.

[^25]:    ${ }^{1} 1$ pound stemmed equal to 1.364 pounds unstemmed.
    ${ }_{2} 1$ pound, unstemmed basis, equal to 1.135 pounds farm-sales weight and 0.905 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.735 pound stemmed processing weight.

[^26]:    See footnotes at end of table.

[^27]:    ${ }^{1} 1$ pound stemmed equal to 1.315 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.07 pounds farm-sales weight and 0.835 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equa lto 0.76 pound stemmed processing weight.

[^28]:    11 pound stemmed equal to 1.300 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.06 pounds farm-sales weight and 0.82 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.77 pound stemmed processing weight.

[^29]:    ${ }^{1} 1$ pound stemmed equal to 1.333 pounds unstemmed.
    21 pound, unstemmed basis, equal to 1.085 pounds farm-sales weight and 0.86 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.75 pound stemmed processing weight.

[^30]:    See footnotes at end of table.

[^31]:    11 pound stemmed equal to 1.224 pounds unstemmed.
    ${ }^{2} 1$ pound, unstemmed basis, equal to 1.135 pounds farm-sales weight and 0.94 pound unstemmed processing weight.
    ${ }^{3} 1$ pound unstemmed processing weight equal to 0.815 pound stemmed processing weight.

[^32]:    ${ }^{1}$ Prior to 1929 stocks of type 62 were not segregated. They were reported in combination with type 45 and are included in the figures in table 21.
    ${ }^{2} 1$ pound stemmed equal to 1.205 pounds unstemmed.
    ${ }^{3} 1$ pound, unstemmed basis, equal to 1.16 pounds farm-sales weight and 0.935 pound unstemmed processing weight.
    ${ }^{4} 1$ pound unstemmed processing weight equal to 0.83 pound stemmed processing weight.
